

WIRELESS COMMUNICATION DEVICE WITH  
AN IMPROVED ANTENNA STRUCTURE

BACKGROUND OF THE INVENTION

1. Field of the Invention

10       The present invention relates to a wireless communication device with an improved antenna structure, and more particularly to a wireless communication device with an improved antenna structure suitable for a high radiation efficiency.

15   2. Description of the Related Art

20       The wireless device of mobile type has an antenna for radiating and receiving radio-waves. FIG. 1 is a schematic perspective view of a mobile telephone with a whip antenna. A mobile telephone 1 has a whip antenna 3 which may be extendable and retractable. In place of the whip antenna 3, a helical antenna fixed to a case of the mobile telephone 1 may alternatively be provided. Further, the antenna may be integrated into the case of the mobile telephone 1.

      The mobile wireless device has a ground which comprises an electrically conductive plate, wherein a power is supplied into between the

ground and the antenna, whereby an electric image is generated. on the  
ground in symmetrical to an electric image on the antenna 3. The antenna  
may comprise a dipole antenna which has a length approximately equal to  
one quarter of the transmitting radio wave. A shield in the case of the  
5 mobile wireless device, a shield covering circuitries or circuit parts, and a  
ground pattern of a printed board may act as the ground. A high frequency  
current flows on a surface of the conductor as the ground. Performances of  
the antenna may be an input impedance and a radiation efficiency. The  
performances of the antenna depend on the current flowing on the ground  
10 plate.

The mobile telephone device may perform a transmission  
operation at a high frequency in the vicinity of 1HGz. A wavelength of the  
radio wave is approximately 30 cm, and a quarter-wavelength of the radio  
wave is thus approximately 7.5 cm. The mobile telephone device is scaled  
15 down so that a width is, for example, about 4cm which is narrower than the  
quarter-wavelength.

Recently developed mobile telephone devices may perform  
transmission operations at a higher frequency near 2GHz, wherein the  
wavelength of the radio wave is approximately 15 cm, and the quarter-  
20 wavelength of the radio wave is thus slightly shorter than 4 cm. The width  
of the case of the mobile telephone is about 4cm which is approximately  
equal to the quarter-wavelength of the radio wave.

As described above, the high frequency current flowing through  
the case of the mobile telephone generates the electric image on the case of

the mobile telephone. FIG. 2 is a schematic view illustrative of a model of the applied high frequency current on the ground plate of the conventional mobile telephone. The antenna 3 is provided at a feeding point which is positioned at a center point on a top side of the ground plate 2. A first  
5 current 5a and a second current 5b from the feeding point on the one side including the feeding point 4 have the same phase and opposite directions, wherein fields generated by the first and second currents 5a and 5b are canceled with each other, whereby effective high frequency currents, which generate the electric image, do not appear in a macroscopic view. As a  
10 result, the electric image to the antenna 3 is not generated on the ground plate 2. This means that the provision of the antenna element 3 in the vicinity of the center position on one side of the ground plate 2 makes the radiation efficiency deteriorated.

In the above circumstances, the development of a novel wireless  
15 device with an improved antenna free from the above problems is desirable.

### SUMMARY OF THE INVENTION

20 Accordingly, it is an object of the present invention to provide a novel wireless device with an improved antenna free from the above problems.

It is a further object of the present invention to provide a novel wireless device with an improved antenna at a suitable position for

avoiding cancellation of high frequency currents on the surface of the ground plate.

It is a still further object of the present invention to provide a novel wireless device with an improved antenna at a suitable position for  
5 improving a radiation efficiency at a high frequency band.

It is yet a further object of the present invention to provide a novel antenna provided on a wireless device free from the above problems.

It is a further object of the present invention to provide a novel antenna provided on a wireless device at a suitable position for avoiding  
10 cancellation of high frequency currents on the surface of the ground plate.

It is a still further object of the present invention to provide a novel antenna provided on a wireless device at a suitable position for improving a radiation efficiency at a high frequency band.

The present invention provides a wireless device including : at  
15 least an antenna ; and at least a conductive ground serving as a ground, through which a high frequency current flows, and the conductive ground having at least a side which is approximately one quarter wavelength of a radio wave transmitted from the antenna, the at least side of the conductive ground having a feeding point, at which the antenna is electrically  
20 connected to the conductive ground, wherein the feeding point on the side is positioned closer to one end of the side than a center position, so that the feeding point is positioned asymmetrical to the conductive ground in any directions included in a plane parallel to the conductive ground, whereby the high frequency current flowing through the conductive ground has an

asymmetrical distribution of current over the conductive ground.

The above and other objects, features and advantages of the present invention will be apparent from the following descriptions.

5 BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments according to the present invention will be described in detail with reference to the accompanying drawings.

FIG. 1 is a schematic perspective view of a mobile telephone  
10 with a whip antenna.

FIG. 2 is a schematic view illustrative of a current path of the applied high frequency current on the ground plate of the conventional mobile telephone.

FIG. 3 is a schematic view illustrative of an internal structure of a  
15 novel wire-less mobile telephone in a first embodiment in accordance with the present invention.

FIG. 4 is a schematic view illustrative of a current path of the applied high frequency current on the ground plate of the novel wire-less mobile telephone of FIG. 3.

FIG. 5 is a schematic view illustrative of an internal structure of a  
20 novel wire-less mobile telephone in a second embodiment in accordance with the present invention.

FIG. 6 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a third embodiment in accordance with

the present invention.

FIG. 7 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a fourth embodiment in accordance with the present invention.

5           FIG. 8 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a fifth embodiment in accordance with the present invention.

#### 10           DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

15           A first aspect of the present invention is a wireless device including : at least an antenna ; and at least a conductive ground serving as a ground, through which a high frequency current flows, and the conductive ground having at least a side which is approximately one  
20           quarter wavelength of a radio wave transmitted from the antenna, the at least side of the conductive ground having a feeding point, at which the antenna is electrically connected to the conductive ground, wherein the feeding point is positioned asymmetrical to the conductive ground in any directions included in a plane parallel to the conductive ground.

20           It is possible that the feeding point on the side is positioned closer to one end of the side than a center position.

          It is possible that the high frequency current flowing through the conductive ground has an asymmetrical distribution of current over the conductive ground.

It is possible that the antenna extends in straight from the feeding point in a direction perpendicular to the side and included in the plane which includes the conductive ground.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part extends in straight from the bending portion in a direction parallel to the side and included in the plane which includes the conductive ground.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part extends from the bending portion in generally U-shape which is included in a plane both vertical to the plane which includes the conductive ground and also parallel to the side.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part extends from the bending portion in open-loop shape which is included in a plane both

vertical to the plane which includes the conductive ground and parallel to the side.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part comprises a plate extending from the bending portion in a plane both vertical to the plane which includes the conductive ground and also parallel to the side.

10 It is possible that the antenna is positioned in a bottom side of the wireless device.

It is possible that the antenna comprises a conductive pattern which is integrated with the conductive ground on a circuit board accommodated in a case of the wireless device.

15 It is possible that the antenna comprises a conductive plate provided on an inner wall of a case of the wireless device.

It is possible that the conductive ground comprises a conductive pattern on a circuit board accommodated in a case of the wireless device. The antenna may be accommodated in a case of the wireless device. The antenna may be accommodated in a bottom space defined between a bottom of the circuit board and a bottom wall of the case. A frequency of the radio wave may be not lower than 1GHz. The wireless device may be a mobile telephone device.

A second aspect of the present invention is a wireless device

including : at least an antenna ; and at least a conductive ground serving as a ground, through which a high frequency current flows, and the conductive ground having at least a side which is approximately one quarter wavelength of a radio wave transmitted from the antenna, the at least side of the conductive ground having a feeding point, at which the antenna is electrically connected to the conductive ground, wherein the feeding point on the side is positioned closer to one end of the side than a center position, so that the feeding point is positioned asymmetrical to the conductive ground in any directions included in a plane parallel to the conductive ground, whereby the high frequency current flowing through the conductive ground has an asymmetrical distribution of current over the conductive ground.

It is possible that the antenna extends in straight from the feeding point in a direction perpendicular to the side and included in the plane which includes the conductive ground.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part extends in straight from the bending portion in a direction parallel to the side and included in the plane which includes the conductive ground.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the

minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part extends from the bending portion in generally U-shape which is included in a plane both  
5 vertical to the plane which includes the conductive ground and also parallel to the side.

It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending  
10 portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part extends from the bending portion in open-loop shape which is included in a plane both vertical to the plane which includes the conductive ground and parallel to the side.

15 It is possible that the antenna comprises a minority part and a majority part bounded by a bending portion from the minority part, and the minority part extends in straight from the feeding point to the bending portion in a direction perpendicular to the side and included in the plane which includes the conductive ground, and the majority part comprises a  
20 plate extending from the bending portion in a plane both vertical to the plane which includes the conductive ground and also parallel to the side.

It is possible that the antenna is positioned in a bottom side of the wireless device.

It is possible that the antenna comprises a conductive pattern

which is integrated with the conductive ground on a circuit board accommodated in a case of the wireless device.

It is possible that the antenna comprises a conductive plate provided on an inner wall of a case of the wireless device.

5 It is possible that the conductive ground comprises a conductive pattern on a circuit board accommodated in a case of the wireless device. The antenna may be accommodated in a case of the wireless device. The antenna may be accommodated in a bottom space defined between a bottom of the circuit board and a bottom wall of the case. A frequency of  
10 the radio wave may be not lower than 1GHz. The wireless device may be a mobile telephone device.

#### FIRST EMBODIMENT:

15 A first embodiment according to the present invention will be described in detail with reference to the drawings. FIG. 3 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a first embodiment in accordance with the present invention. FIG. 4 is a schematic view illustrative of a current path of the applied high frequency current on the ground plate of the novel wire-less mobile  
20 telephone of FIG. 3.

A wire-less mobile telephone has a case 1, which accommodates a circuit board, a feeding point 4 on a bottom side of the board, and an antenna 3 extending from the feeding point 4 downwardly in straight. The feeding point 4 is positioned closer to one end of the bottom side than a

center position of the bottom side. The board has a ground pattern 2 having a ground potential. An electric image symmetrical with reference to the antenna 3 is formed on the ground pattern 2.

5 A high frequency current flows on the ground pattern 2 as the surface of the board. First and second high frequency currents 5a and 5b separated at the feeding point 4 flow at the same phase and opposite directions to each other on the bottom side of the ground pattern 2. A first current path for the first high frequency current 5a on the bottom side of the ground pattern 2 is much shorter than a second current path for the second high frequency current 5b on the bottom side of the ground pattern 2. The field generated by the first high frequency current 5a on the first current path of the bottom side of the ground pattern 2 is canceled with a minority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2. The remaining majority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2 is, however, not cancelled.

20 In addition to the ground pattern 2 of the board, a shield of the case 1 and a shield for covering the circuitries or circuit parts on the circuit board also serve as ground. The most outer one of the ground pattern and the shields mainly serves as the conductive ground, on which the electric image to the antenna 3 is generated. The antenna 3 extends from the feeding point 4 which is asymmetrical to the conductive ground in any directions, for example, both horizontal and vertical directions for avoiding cancellation of a majority of the high frequency currents on the conductive

ground. Namely, the conductive ground has an asymmetrical distribution of the high frequency currents with reference to the antenna 3 for avoiding cancellation of a majority of the high frequency currents on the conductive ground, thereby allowing generation of an electric image on the conductive  
5 ground to the antenna 3, resulting in an improvement in the radiation efficiency of the antenna.

The antenna 3 projecting downwardly does not disturb telephone user in telephone conversions.

10 SECOND EMBODIMENT:

A second embodiment according to the present invention will be described in detail with reference to the drawing. FIG. 5 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a second embodiment in accordance with the present  
15 invention.

A wire-less mobile telephone has a case 1, which accommodates a circuit board and an antenna 6, a feeding point 4 on a bottom side of the board. The antenna 3 has a bending point 6. The antenna 3 is included in a plane which includes the ground pattern 2 of the circuit board. The antenna  
20 3 comprises a minority part extending from the feeding point 4 downwardly up to the bending point 6 and a majority part extending from the bending point 6 horizontally, so that the majority part of the antenna 3 extends horizontally in straight and in parallel to the bottom side of the ground pattern 2, provided that the majority of the antenna 3 is spaced from

the bottom side of the ground pattern 2 at a distance defined by a short length of the minority part. The feeding point 4 is positioned closer to a first end of the bottom side than a center position of the bottom side. The majority of the antenna 3 extends horizontally in straight toward a second  
5 end opposite to the first end of the bottom side of the ground pattern 2. An electric image symmetrical with reference to the antenna 3 is formed on the ground pattern 2.

A high frequency current flows on the ground pattern 2 as the surface of the board. First and second high frequency currents 5a and 5b  
10 separated at the feeding point 4 flow at the same phase and opposite directions to each other on the bottom side of the ground pattern 2. A first current path for the first high frequency current 5a on the bottom side of the ground pattern 2 is much shorter than a second current path for the second high frequency current 5b on the bottom side of the ground pattern 2. The  
15 field generated by the first high frequency current 5a on the first current path of the bottom side of the ground pattern 2 is canceled with a minority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2. The remaining majority part of the second high frequency current 5b on the second current path of the bottom  
20 side of the ground pattern 2 is, however, not cancelled.

In addition to the ground pattern 2 of the board, a shield of the case 1 and a shield for covering the circuitries or circuit parts on the circuit board also serve as ground. The most outer one of the ground pattern and the shields mainly serves as the conductive ground, on which the electric

image to the antenna 3 is generated. The antenna 3 extends from the feeding point 4 which is asymmetrical to the conductive ground in any directions, for example, both horizontal and vertical directions for avoiding cancellation of a majority of the high frequency currents on the conductive ground. Namely, the conductive ground has an asymmetrical distribution of the high frequency currents with reference to the antenna 3 for avoiding cancellation of a majority of the high frequency currents on the conductive ground, thereby allowing generation of an electric image on the conductive ground to the antenna 3, resulting in an improvement in the radiation efficiency of the antenna.

The antenna 3 does not project from the case 1 and also does extend in the plane including the ground pattern 2, so that a further size reduction of the mobile wireless telephone device can be obtained.

As a modification to the second embodiment, it is also possible that the antenna 3 may comprise a conductive pattern which is provided on the circuit board together with the ground pattern 2. Namely, the conductive pattern serving as the antenna 3 and the ground pattern 2 serving as the conductive ground are integrated on the single circuit board accommodated in the case 1. This modified arrangement of the antenna may allow a further reduction in size of the mobile wireless telephone device. The antenna is not a separate part from the circuit board for a reduction in the number of the necessary parts of the mobile wireless telephone device.

10007015-120401

THIRD EMBODIMENT:

A third embodiment according to the present invention will be described in detail with reference to the drawing. FIG. 6 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a third embodiment in accordance with the present invention.

10007015-120401  
A wire-less mobile telephone has a case 1, which accommodates a circuit board and an antenna 6, a feeding point 4 on a bottom side of the board. The antenna 3 has a bending point 6. The antenna 3 comprises a minority part extending from the feeding point 4 downwardly up to the bending point 6 and a majority part extending from the bending point 6 horizontally, so that the majority part of the antenna 3 extends horizontally in generally U-shape and in parallel to the bottom side of the ground pattern 2, provided that the majority of the antenna 3 is spaced from the bottom side of the ground pattern 2 at a distance defined by a short length of the minority part. The generally U-shaped majority part of the antenna 3 is included in a plane vertical to the ground pattern 2. The feeding point 4 is positioned closer to a first end of the bottom side than a center position of the bottom side. An electric image symmetrical with reference to the antenna 3 is formed on the ground pattern 2.

20 A high frequency current flows on the ground pattern 2 as the surface of the board. First and second high frequency currents 5a and 5b separated at the feeding point 4 flow at the same phase and opposite directions to each other on the bottom side of the ground pattern 2. A first current path for the first high frequency current 5a on the bottom side of the

ground pattern 2 is much shorter than a second current path for the second high frequency current 5b on the bottom side of the ground pattern 2. The field generated by the first high frequency current 5a on the first current path of the bottom side of the ground pattern 2 is canceled with a minority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2. The remaining majority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2 is, however, not cancelled.

In addition to the ground pattern 2 of the board, a shield of the case 1 and a shield for covering the circuitries or circuit parts on the circuit board also serve as ground. The most outer one of the ground pattern and the shields mainly serves as the conductive ground, on which the electric image to the antenna 3 is generated. The antenna 3 extends from the feeding point 4 which is asymmetrical to the conductive ground in any directions, for example, both horizontal and vertical directions for avoiding cancellation of a majority of the high frequency currents on the conductive ground. Namely, the conductive ground has an asymmetrical distribution of the high frequency currents with reference to the antenna 3 for avoiding cancellation of a majority of the high frequency currents on the conductive ground, thereby allowing generation of an electric image on the conductive ground to the antenna 3, resulting in an improvement in the radiation efficiency of the antenna.

Even the antenna 3 is longer than the quarter-wavelength of the radio wave and also longer than the width of the case 1 of the mobile

wireless telephone device, the antenna 3 does not project from the case 1 and also does extend in the plane including the ground pattern 2, so that a further size reduction of the mobile wireless telephone device can be obtained.

5           As a modification to the third embodiment, it is also possible that the antenna 3 may comprise a conductive pattern which extends over a first surface of the circuit board together with the ground pattern 2 as well as extends through a through hole of the circuit board and further extends over a second surface of the circuit board. Namely, the conductive pattern  
10       serving as the antenna 3 and the ground pattern 2 serving as the conductive ground are integrated on the single circuit board accommodated in the case 1. This modified arrangement of the antenna may allow a further reduction in size of the mobile wireless telephone device. The antenna is not a separate part from the circuit board for a reduction in the number of the  
15       necessary parts of the mobile wireless telephone device.

#### FOURTH EMBODIMENT:

A fourth embodiment according to the present invention will be described in detail with reference to the drawing. FIG. 7 is a schematic  
20       view illustrative of an internal structure of a novel wire-less mobile telephone in a fourth embodiment in accordance with the present invention.

A wire-less mobile telephone has a case 1, which accommodates a circuit board and an antenna 6, a feeding point 4 on a bottom side of the board. The antenna 3 has a bending point 6. The antenna 3 comprises a

minority part extending from the feeding point 4 downwardly up to the bending point 6 and a majority part extending from the bending point 6 horizontally, so that the majority part of the antenna 3 extends horizontally in generally open-loop shape and in parallel to the bottom side of the ground pattern 2, provided that the majority of the antenna 3 is spaced from the bottom side of the ground pattern 2 at a distance defined by a short length of the minority part. The generally open-loop shaped majority part of the antenna 3 is included in a plane vertical to the ground pattern 2. The feeding point 4 is positioned closer to a first end of the bottom side than a center position of the bottom side. An electric image symmetrical with reference to the antenna 3 is formed on the ground pattern 2.

A high frequency current flows on the ground pattern 2 as the surface of the board. First and second high frequency currents 5a and 5b separated at the feeding point 4 flow at the same phase and opposite directions to each other on the bottom side of the ground pattern 2. A first current path for the first high frequency current 5a on the bottom side of the ground pattern 2 is much shorter than a second current path for the second high frequency current 5b on the bottom side of the ground pattern 2. The field generated by the first high frequency current 5a on the first current path of the bottom side of the ground pattern 2 is canceled with a minority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2. The remaining majority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2 is, however, not cancelled.

In addition to the ground pattern 2 of the board, a shield of the case 1 and a shield for covering the circuitries or circuit parts on the circuit board also serve as ground. The most outer one of the ground pattern and the shields mainly serves as the conductive ground, on which the electric image to the antenna 3 is generated. The antenna 3 extends from the feeding point 4 which is asymmetrical to the conductive ground in any directions, for example, both horizontal and vertical directions for avoiding cancellation of a majority of the high frequency currents on the conductive ground. Namely, the conductive ground has an asymmetrical distribution of the high frequency currents with reference to the antenna 3 for avoiding cancellation of a majority of the high frequency currents on the conductive ground, thereby allowing generation of an electric image on the conductive ground to the antenna 3, resulting in an improvement in the radiation efficiency of the antenna.

Even the antenna 3 is longer than the quarter-wavelength of the radio wave and also longer than the width of the case 1 of the mobile wireless telephone device, the antenna 3 does not project from the case 1 and also does extend in the plane including the ground pattern 2, so that a further size reduction of the mobile wireless telephone device can be obtained.

As a modification to the fourth embodiment, it is also possible that the antenna 3 may comprise a conductive pattern which extends over a first surface of the circuit board together with the ground pattern 2 as well as extends through a first through hole of the circuit board and further

extends over a second surface of the circuit board and further extends a second through hole of the circuit board. Namely, the conductive pattern serving as the antenna 3 and the ground pattern 2 serving as the conductive ground are integrated on the single circuit board accommodated in the case 1. This modified arrangement of the antenna may allow a further reduction in size of the mobile wireless telephone device. The antenna is not a separate part from the circuit board for a reduction in the number of the necessary parts of the mobile wireless telephone device.

10 FIFTH EMBODIMENT:

A fifth embodiment according to the present invention will be described in detail with reference to the drawing. FIG. 8 is a schematic view illustrative of an internal structure of a novel wire-less mobile telephone in a fifth embodiment in accordance with the present invention.

15 A wire-less mobile telephone has a case 1, which accommodates a circuit board and an antenna 6, a feeding point 4 on a bottom side of the board. The antenna 3 has a bending point 6. The antenna 3 comprises a minority part extending from the feeding point 4 downwardly up to the bending point 6 and a majority part extending from the bending point 6 horizontally, so that the majority part of the antenna 3 comprises an expanded part which extends horizontally in generally rectangle plane and in parallel to the bottom side of the ground pattern 2, provided that the majority of the antenna 3 is spaced from the bottom side of the ground pattern 2 at a distance defined by a short length of the minority part. The

feeding point 4 is positioned closer to a first end of the bottom side than a center position of the bottom side. An electric image symmetrical with reference to the antenna 3 is formed on the ground pattern 2.

5 A high frequency current flows on the ground pattern 2 as the surface of the board. First and second high frequency currents 5a and 5b separated at the feeding point 4 flow at the same phase and opposite directions to each other on the bottom side of the ground pattern 2. A first current path for the first high frequency current 5a on the bottom side of the ground pattern 2 is much shorter than a second current path for the second  
10 high frequency current 5b on the bottom side of the ground pattern 2. The field generated by the first high frequency current 5a on the first current path of the bottom side of the ground pattern 2 is canceled with a minority part of the second high frequency current 5b on the second current path of the bottom side of the ground pattern 2. The remaining majority part of the  
15 second high frequency current 5b on the second current path of the bottom side of the ground pattern 2 is, however, not cancelled.

In addition to the ground pattern 2 of the board, a shield of the case 1 and a shield for covering the circuitrics or circuit parts on the circuit board also serve as ground. The most outer one of the ground pattern and  
20 the shields mainly serves as the conductive ground, on which the electric image to the antenna 3 is generated. The antenna 3 extends from the feeding point 4 which is asymmetrical to the conductive ground in any directions, for example, both horizontal and vertical directions for avoiding cancellation of a majority of the high frequency currents on the conductive

ground. Namely, the conductive ground has an asymmetrical distribution of the high frequency currents with reference to the antenna 3 for avoiding cancellation of a majority of the high frequency currents on the conductive ground, thereby allowing generation of an electric image on the conductive ground to the antenna 3, resulting in an improvement in the radiation efficiency of the antenna.

Even the antenna 3 is longer than the quarter-wavelength of the radio wave and also longer than the width of the case 1 of the mobile wireless telephone device, the antenna 3 does not project from the case 1 and also does extend in the plane vertical to the ground pattern 2, so that a further size reduction of the mobile wireless telephone device can be obtained.

The expanded majority part of the antenna 3 increases a wide band of the available frequency and improves a voltage standing wave ratio (VSWR).

As a modification to the fifth embodiment, it is also possible that the antenna 3 may comprise a conductive pattern which extends over the bottom face of the case 1. Alternatively, the antenna 3 may comprise another conductive pattern which extends over the circuit board together with the ground pattern 2. Namely, the conductive pattern serving as the antenna 3 and the ground pattern 2 serving as the conductive ground are integrated on the single circuit board accommodated in the case 1. This modified arrangement of the antenna may allow a further reduction in size of the mobile wireless telephone device. The antenna is not a separate part

from the circuit board for a reduction in the number of the necessary parts of the mobile wireless telephone device.

Although the invention has been described above in connection with several preferred embodiments therefor, it will be appreciated that  
5 those embodiments have been provided solely for illustrating the invention, and not in a limiting sense. Numerous modifications and substitutions of equivalent materials and techniques will be readily apparent to those skilled in the art after reading the present application, and all such modifications and substitutions are expressly understood to fall within the true scope and  
10 spirit of the appended claims.
